

Observations of the Diurnal Cycle of Marine Stratocumulus Clouds and Precipitation

Casey Burleyson¹, Sandra Yuter¹,
and Simon de Szoeke²

¹ North Carolina State University

² Oregon State University

Goals

- 1) Document the diurnal variation of important features of the cloud deck to aid in validation of model output.
- 2) Examine to what degree drizzle varies in time and space.
- 3) Begin to understand the controlling factors that cause drizzle to start and stop.

Data from the R.H. Brown

Data were divided into two regions, east and west of 80°W, to account for longitudinal changes to boundary layer characteristics.

Potential Temperature

C-Band Radar Observed Drizzle

Drizzle Cells Per Scan

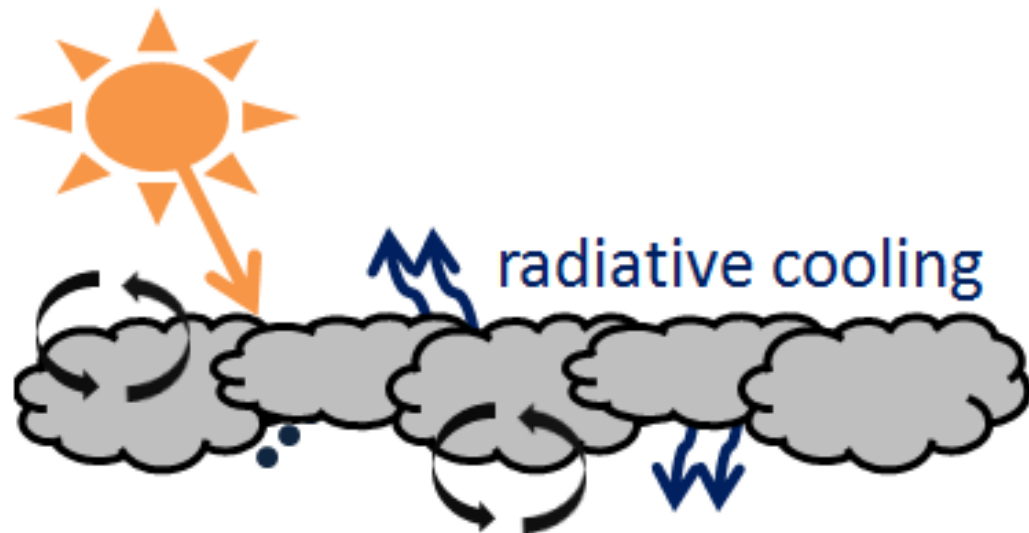

Drizzle Area Per Scan

Noon

$h_c =$ cloud depth

$h_{ML} =$ mixed layer depth

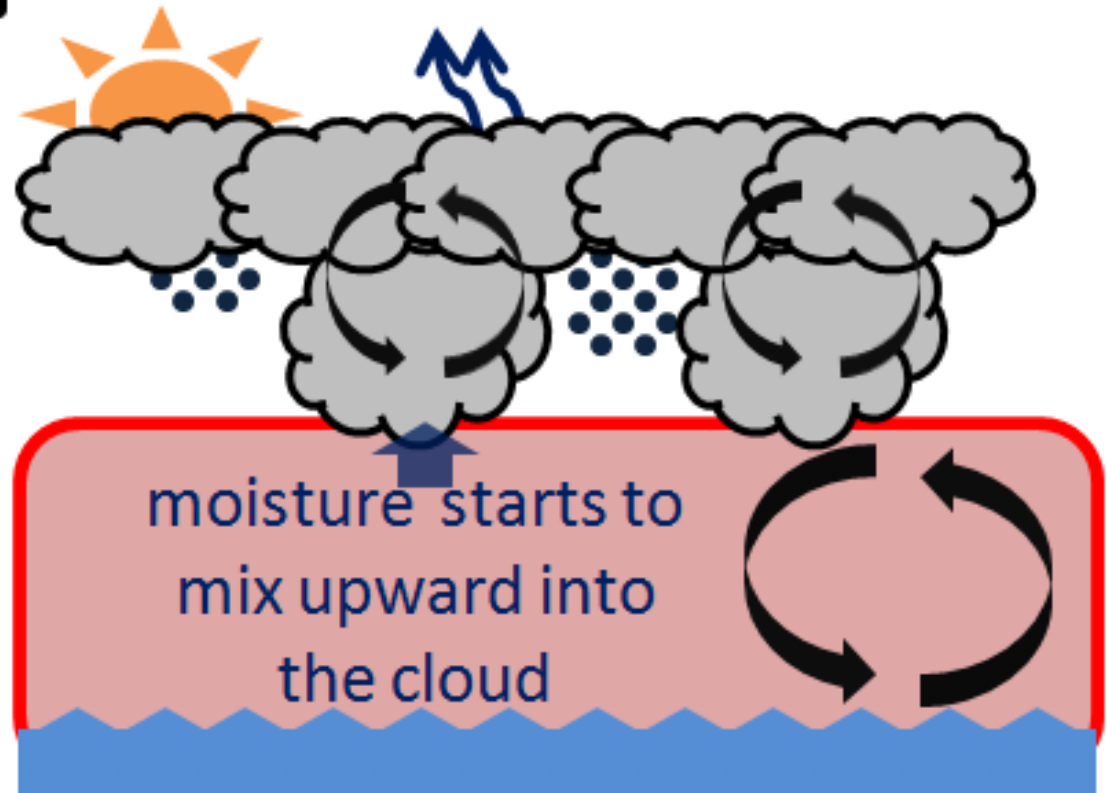

The surface mixed layer is decoupled from the cloud deck.

Sunset

$$\frac{d(h_c)}{dt} > 0$$

$$\frac{d(\text{precip})}{dt} > 0$$

$$\frac{d(h_{ML})}{dt} > 0$$

The mixed layer is deeper and may be coupled with the cloud deck via cumulus clouds.

9 pm -Midnight

$$\frac{d(h_c)}{dt} > 0$$
$$\frac{d(\text{precip})}{dt} > 0$$
$$\frac{d(h_{ML})}{dt} > 0$$

The boundary layer is coupled through cloud top radiative cooling and cellular convection.

Heavy Drizzle (West)

Midnight - 3 am

$$\frac{d(h_c)}{dt} = 0$$

precip = max

$$\frac{d(h_{ML})}{dt} = 0$$

Diurnal maximum in precipitation and degree of coupling. Some drizzle evaporates.

Heavy Drizzle (West)

3 am - 6 am

$$\frac{d(h_C)}{dt} \sim 0$$
$$\frac{d(\text{precip})}{dt} < 0$$
$$\frac{d(h_{ML})}{dt} \sim 0$$

An evaporatively cooled stable layer develops and moisture flux into cloud is reduced.

Sunrise - Noon

$$\frac{d(h_c)}{dt} \ll 0$$
$$\frac{d(\text{precip})}{dt} \ll 0$$
$$\frac{d(h_{ML})}{dt} < 0$$

Solar heating offsets radiative cooling and the boundary layer becomes less coupled.

Conclusions

- 1) The diurnal cycle is clearly evident in every variable examined. Diurnal fluctuations in cloud depth, precipitation, and boundary layer mixing should be key features in simulations of STBLs.
- 2) Overnight the cloud depth is similar over all longitudes. The cloud deck thins rapidly after sunrise.
- 3) Heavy drizzle that occurs in the west is self-limiting, maximizing near 3 am. Lighter drizzle in the east only diminishes after the sun comes up.

Noon

$h_c = \text{cloud depth}$
 $h_{ML} = \text{mixed layer depth}$

radiative cooling

surface mixed layer

turbulent mixing

ocean

The surface mixed layer is decoupled from the cloud deck.

Sunset

$\frac{d(h_c)}{dt} > 0$
 $\frac{d(\text{precip})}{dt} > 0$
 $\frac{d(h_{ML})}{dt} > 0$

moisture starts to mix upward into the cloud

The mixed layer is deeper and may be coupled with the cloud deck via cumulus clouds.

9 pm - Midnight

$\frac{d(h_c)}{dt} > 0$
 $\frac{d(\text{precip})}{dt} > 0$
 $\frac{d(h_{ML})}{dt} > 0$

Moisture

Downdrafts

The boundary layer is coupled through cloud top radiative cooling and cellular convection.

Heavy Drizzle (West)

Midnight - 3 am

$\frac{d(h_c)}{dt} = 0$
 $\text{precip} = \text{max}$
 $\frac{d(h_{ML})}{dt} = 0$

evaporative cooling & outflows

Diurnal maximum in precipitation and degree of coupling. Some drizzle evaporates.

Heavy Drizzle (West)

3 am - 6 am

$\frac{d(h_c)}{dt} \sim 0$
 $\frac{d(\text{precip})}{dt} < 0$
 $\frac{d(h_{ML})}{dt} \sim 0$

stable

An evaporatively cooled stable layer develops and moisture flux into cloud is reduced.

Sunrise - Noon

$\frac{d(h_c)}{dt} \ll 0$
 $\frac{d(\text{precip})}{dt} \ll 0$
 $\frac{d(h_{ML})}{dt} < 0$

moisture begins to increase

Solar heating offsets radiative cooling and the boundary layer becomes less coupled.
